

IranBot is a self-branded ("IRAN-BOTNET", "death to Israel") ARM/Linux and x86_64 DDoS botnet tracked across three distinct builds between June and July 2026. Attribution is by code, not the branding. Over six weeks the family shed its command encryption, its polish, and its branding while gaining a telnet backdoor and then self-propagation, and it never reused command-and-control infrastructure. It is a disposable operation: build cheap, burn fast, move on.

Report

The full analysis is in report.md: a build-by-build account of the family's devolving encryption, rising propagation capability, and throwaway infrastructure, plus detection guidance and indicators.

Technical summary

Builds: armv7l 62e424b2 (Jun 8), x86_64 7e4d2b3b (Jul 9), x86_64 self-replicating b1a6dba6 (Jul 20)

Command channel: bespoke #C cipher (armv7l) devolving to plain XOR then plaintext

Attack methods: 7 (armv7l) reduced to 3 (http/icmp/udpplain) in the x86_64 builds

Self-propagation: telnet default-credential scanner + Realtek SDK exploit (self-replicating build only)

Backdoors: persistent telnet bindshell (7e4d2b3b); on-demand !openshell (b1a6dba6)

Infrastructure: never reused; five distinct ASNs across the operation (VPSVAULT, SWISSNET, BANATSYNC, Fiba Cloud, SkyPass)
